Interface adapters - entry point for the users of your app. They wrap around an application core and adapt its input/output to a delivery mechanism, ie. HTTP Controllers, HTML Presenters, JSON REST Controllers, GraphQL Resolvers or CLI access, etc

Infrastructure adapters wrap around external APIs/Databases/technologies/libraries and adapt its input/output to a port, abstracting away external dependencies to make your domain technology agnostic.

Core's Domain (inner) layer:

Entities - contain domain business logic and attributes and has an identity (id).

Aggregates - similar to entities, but encapsulate a cluster of domain objects

Value Objects - wrap one or multiple attributes and the logic associated with those attributes; has no identity.

Domain Services - orchestrates domain logic between multiple Entities.

Core's Application (outer) layer:

Ports are interfaces that create boundaries of the domain to abstract away external tech or I/O. Implemented by adapters

Application Services - orchestrates application flow; accesses outside world through ports to fetch/save Entities, emit events and execute Domain Logic on Entities/Aggregates
